

Top: population = mean best dF/F of the signal-like ROIs, high-passed > 30 s, baseline -2..0 s subtracted; dashed line = loom onset; grey = response window 0-4 s; white lines in the trial raster separate blocks.
b: each ROI averaged over the trials, sorted by its 0-4 s response. Movement removed = face + whisking + ball ridge model fitted outside all stimulus windows and subtracted (pupil not used: it reflects the stimulus).
e, f: rows ordered by raw z (trials in brackets); z = response against onsets circularly shifted inside their own block (1000 draws). Examples: largest responses (columns 1, 2, 4) and a matched receding disc (3).
Pupil, face and whisking are high-passed z. Marker shape = animal (circle RB24, square RB23, triangle RB22), hollow / † = flagged (not pooled).
