

Response = mean(axon, window after onset) - mean(baseline) per trial, population mean of the signal-like ROIs high-passed > 30 s; windows: flash 0-2 s, bar 0.5-4 s, loom 0-4 s, square 0-3 s.
Null: onsets circularly shifted inside their own block (1000 draws). Movement removed = ridge model of face motion + whisking + ball (lags -1..+3 s) fitted outside all stimulus windows and subtracted;
pupil is deliberately not used (flashes constrict the pupil: a pupil-adjusted residual would be spurious). Marker shape = animal, filled = unflagged, hollow / dashed = flagged (not pooled);
black bars = mean of per-animal means with 95% hierarchical bootstrap CI (at most 3 mice, most stimuli 2-3).
